(54) Nickel-based catalyst, its preparation and its application.

(57) The invention provides nickel-based catalysts suitable for hydrogenation reactions comprising a water soluble, silica containing carrier material amounting to 90-10 parts by weight and 10-90 parts by weight of nickel/nickel compound, having an overall active nickel surface of 70-200 m²/g, nickel/nickel compound aggregates with an average particle size of 2-100 micrometers, which aggregates are for at least 60%, preferably for at least 80% free of carrier particles. The average nickel crystallite size is preferably between 0.5 and 10 nanometers, more preferably between 1 and 3 nanometers. The catalysts can be prepared in a multistep process involving rapid precipitation of nickel compound, an insoluble carrier and a distinct, much longer ageing step followed by separation of solids, drying and activation.

NICKEL-BASED CATALYST, ITS PREPARATION AND ITS APPLICATION

The invention relates to a nickel-based catalyst, to its preparation and to its application for hydrogenation reactions.

5 Nickel-based catalysts are well-known and are widely used as hydrogenation catalysts. It is customary to prepare them by precipitating nickel-hydroxide and/or -carbonate from an aqueous solution of a nickel salt using an alkaline reactant, often in the presence of a
10 carrier.

In the preparation of these catalysts measures are often taken to precipitate the insoluble nickel compounds as gradually as possible from the solution onto
15 the carrier particles suspended therein. To this end, for example, a carrier suspension in a solution of a nickel-ammonia complex is heated so as to allow the ammonia to escape, thereby causing the nickel to precipitate (cf. GB-A-926 235). Alternatively, urea is
20 incorporated in the solution in which the carrier is suspended, after which the urea is decomposed by heating (cf. GB-A-1 220 105), causing the nickel hydroxide to precipitate. The aim of this very gradual precipitation of the nickel is to cover the carrier particles
25 entirely or largely with nickel compound. Furthermore, GB-A-1 367 088 discloses the preparation of a catalyst by precipitating nickel on guhr, keeping temperature, pH, alkalinity and residence time within narrow ranges. In this process the nickel hydroxide is slowly precipi-
30 tated from a diluted solution in a reaction vessel, after which the solid components are separated. Precipitation and post-reaction (the latter normally being referred to as "ageing") take place in the same reaction

vessel, which therefore has to be relatively big, under the same reaction conditions.

It has now been found however that new, improved
5 nickel-based catalysts can be prepared by carrying out this process in at least two separate steps, to wit:
(i) A very rapid precipitation step, in which under vigorous agitation the nickel hydroxide/carbonate is precipitated in a precipitation reactor with a mean
10 residence time of 0.01 to 10, preferably 0.2 to 4.5 minutes, rather even less than 3.5 minutes, during which the normality of the solution in the reactor, containing excess alkali, is between 0.05 and 0.5, preferably between 0.1 and 0.3 N and the temperature
15 of the liquid in the precipitation reactor is kept between 5 and 95°, preferably between 20 and 55°C.
(ii) At least one separate, longer ageing step with a mean residence time in the post-reactor of 20 to 180 min, and a temperature that remains between 60 and 100°,
20 preferably between 90 and 98°C. It is sometimes preferred for the temperature during the ageing step(s) to differ from that during the precipitation step; in particular it may be advantageous to perform the ageing step at somewhat higher temperatures, e.g. with a
25 difference of 10°C above the precipitation temperature.

The nickel-based catalysts according to the present invention comprise a water-insoluble carrier material which is present or added during preparation. Suitable
30 carrier materials are, for example, silica-containing materials such as kieselguhr, aluminium trioxide, and silicates such as bentonite. Kieselguhr is the preferred material, particularly kieselguhr containing from 50 to 90 wt.% of amorphous silica.

35

The carrier material can be added (a) directly as such, (b) as an aqueous suspension, (c) preferably as a sus-

pension in an aqueous nickel salt solution, (d) as a suspension in an aqueous solution of the alkaline compound.

- 5 According to embodiments (a) - (d) the carrier can be added before or during precipitation. According to embodiments (a), (b) or (d), however, the carrier can also be added entirely or partly (the latter being preferred) after precipitation, but also before or during
10 ageing.

After precipitation and ageing according to the invention the solids are separated from the liquid, optionally washed, dried and activated by contacting them
15 with hydrogen at an elevated temperature in a manner known per se.

Nickel compounds which can be used as starting materials for the preparation of the catalysts according
20 to the present invention are water-soluble nickel compounds such as nitrate, sulphate, acetate and chloride. The solutions that are fed into the precipitation reactor preferably contain between 10 and 80 g nickel per litre; particularly preferred is the use of solutions
25 containing between 25 and 60 g nickel per litre.

Alkaline compounds which can be used as starting material in the process according to the present invention are alkalimetal hydroxides, alkalimetal carbonate, alkalimetal bicarbonate, the corresponding ammonium compounds and mixtures of the above-mentioned compounds.
30 The concentration of the alkaline solution fed into the precipitation reactor is preferably 20-300 g of anhydrous material per litre (as far as the solubility permits this), particularly between 50 and 250 g per
35 litre.

It has practical advantages to use the two solutions (nickel-containing and alkaline, respectively) in about equal concentrations expressed in equivalents, resulting in the use of about equal volumes.

5

The nickel-containing solution and the alkaline solution are fed at such rates that a slight excess of alkaline compound is present during the precipitation step, namely such that the normality of the liquid ranges from 0.05 to 0.5, preferably from 0.1 to 0.3 (said normality being determined by titration with aqueous hydrochloric acid using methylorange as the indicator). In the ageing step it may sometimes be desirable to add further alkaline solution in order to maintain the alkalinity (normality) in the above-defined range.

The precipitation reactor comprises a means for vigorous agitation of the reacting fluid and its dimensions are such in relation to the amounts of fluid fed that the short mean residence times indicated can be obtained. Preferred mean residence times in the precipitation reactor are normally between 0.01 and 10, particularly between 0.2 and 4.5 minutes. The precipitation step and also the ageing step can be carried out batchwise, continuously and semi-continuously (e.g. according to the cascade method).

In the preferred continuous precipitation process (step i) the rate of addition of the solutions to the precipitation reactor is controlled by continuously or discontinuously measuring the alkalinity (normality) of the discharged liquid. This can sometimes also be done by monitoring the pH. Also the temperatures of the reacting liquids fed into the precipitation reactor are used to control the temperature at which precipitation takes place. The required vigorous agita-

tion of the liquid in the precipitation reactor preferably takes place with an energy input of 5-25 K watts per 1000 kg of solution. Jet mixing is also a suitable method, involving much larger specific energy inputs of up to 2000 K watts/kg.

The reaction mixture obtained from the precipitation reactor is subsequently led into a significantly larger post-reactor, in which the liquid is further agitated. If desired, additional ingredients can be incorporated here, such as carrier material, alkaline solution as defined hereinbefore and/or possibly promoters.

Preferably the temperature of the liquid in the post-reactor, i.e. during the ageing step, is kept at a temperature between 60 and 100°C, preferably between 90 and 98°C.

The normality of the liquid in the post-reactor during the ageing step (step ii) is kept in the same range as during the precipitation step (step i); it may be required to add some further alkali. The ageing step can be performed in one or more post-reactors, the (overall) mean residence time being kept between 20 and 180 min, preferably between 60 and 150 min. If two or more post-reactors are used it is desirable to arrange this in such a way that in the second or following post-reactor the temperature of the liquid is 10 to 15 centigrades below the temperature in the first post-reactor.

After completion of the ageing step the solids are separated from the mother liquor, usually washed, dried, optionally ground and/or calcinated and subsequently activated with hydrogen gas at an elevated temperature usually ranging between 250 and 500°, preferably between 300 and 400°C. This activation can take place at

atmospheric or higher pressure. Atmospheric pressure is preferred.

5 Preferably before drying, or during any previous step promoters can conveniently be added. Promoters comprise amounts of 0.05 to 10%, calculated on the weight of nickel, of metals/compounds such as copper, cobalt, zirconium, molybdenum, silver, magnesium, any other metals and combinations thereof.

10

The separated solid is preferably washed with water, sometimes made slightly alkaline, or water with a detergent added thereto.

15 Organic solvents can sometimes be used advantageously. Drying takes place preferably with forced air circulation. Spray-drying and freeze-drying are also quite well possible.

20 The present invention provides new, improved nickel-based catalysts which comprise 10-90 parts by weight of nickel/nickel compounds and 90-10 parts by weight of insoluble carrier material, as well as 0-10, preferably 0.05-5 parts by weight of a metal promoter, which catalysts have an active nickel surface of 70-200 m²/g, preferably more than 100 m²/g, said catalysts further comprising aggregates which mainly consist of nickel/nickel compounds with an average particle size of 2 to 100 micrometers, preferably between 5 and 25 micrometers, and which aggregates have an (outer) surface which is for at least 60% free of carrier particles attached thereto. Preferably the nickel/nickel compound aggregates have a surface which is for more than 80%, particularly for more than 90% free of carrier particles.

25

30

35

The nickel/nickel compound aggregates consist mainly, i.e. for more than 80%, preferably more than 90%, of nickel and nickel oxides, but some promoter material may also be present. These aggregates preferably contain nickel crystallites with an average diameter between 0.5 and 10, more particularly between 1 and 3 nanometers.

The catalyst according to the invention is used for the hydrogenation of unsaturated organic compounds, in particular oils and fats, fatty acid and derivatives thereof.

The invention is illustrated by the following Examples.

Example 1

An aqueous suspension was prepared by suspending kieselguhr (containing 7.0% amorphous SiO_2) in a NiSO_4 solution (35 g Ni/l and 1.2 N), in such a way that the Ni: SiO_2 -ratio was 1:2.3. Also an aqueous soda solution, containing 75 g of Na_2CO_3 (anh) per litre and 1.4 N, was prepared. Subsequently both solutions were continuously pumped into a vigorously agitated pump reactor, in about equal volumes, resulting in precipitation of nickelhydroxide/carbonate at a temperature of 80°C. The alkalinity of the suspension so obtained was 0.096 N. In the reactor in which the precipitation took place the suspension had a residence time of 4 minutes, after which the suspension was immediately passed to the first of a series of two post-reactors. In each of these post-reactors the precipitate was aged for 50 minutes (mean residence time) at temperatures of 97° and 80°C, respectively. The aged precipitate was then continuously filtered off and the green filter cake thus obtained was washed with

water, dried and activated with hydrogen under atmospheric pressure at a temperature of 350°C.

5 Electron microscopy and microröntgen analysis showed
that the catalyst consisted of nickel crystallites
averaging 2 nanometers and aggregates averaging 21 micrometers. The surface of the nickel/nickel compound
aggregates was for about 85% free of carrier particles
and also the original shape of the siliceous skeletons
10 was largely uncovered and well and freely perceptible.

Examples 2-7

Following the procedure as described in Example 1
further catalysts were prepared according to the invention,
15 while varying the amounts and conditions, as
is shown in Table I. Measures were taken to keep the
other conditions unchanged.

20 In Table II, showing the hydrogenation characteristics
of this catalyst, comparisons are made with a catalyst
known from the literature.

On fatty acid hydrogenation it was found that for
achieving a certain iodine value, with catalysts according
25 to the invention less than half the hydrogenation
time was sufficient and that in the case of fish
oil the catalyst also retained its activity for a longer
period. From the melting points it appeared that the new
catalyst had a greater selectivity, i.e. less tri-saturated
30 triglyceride was formed.

On fatty acid hydrogenation it turned out that hydrogenation
could be carried through to lower iodine
values in the same hydrogenation time and thus proceeded
35 more rapidly than with the known catalyst used
for comparison. Furthermore, the hydrogenations can
also be performed with excellent results at a lower

hydrogenation temperature. In addition, the new catalyst could be filtered very effectively, in any case better than the known catalyst.

- 5 Table III below gives an impression of fatty acid hydrogenation plotted against time (relation between iodine value and hydrogenation time under otherwise equal conditions).

10

TABLE III

15

20

Hydrogenation time (min)	Iodine value with catalyst 4 (Table II)	Iodine value with known catalyst (Table II)
30	45.1	72.1
60	15.3	45.5
90	9.8	22.2
120	5.3	17.8
150	3.3	15.1

25

Table III demonstrates that the iodine value of the hydrogenated fatty acid of about 15.2, obtained with the conventional catalyst widely used for this purpose after about 150 minutes, was already reached in about 60 minutes with the catalyst according to the invention, which is a considerable technological improvement.

Mean resid. time (step 2) in minutes	50/50	50/50	50	50/50	85/50	30	30
Excess alkali (mol/l)	0.135/ 0.192*	--	--	--	--	--	--
* = extra alkali							

Catalysts 1-5 contained 70% nickel and 30% SiO₂; catalysts 6 and 7 contained 64% nickel and 36% SiO₂.

Active nickel surfaces ranged between 120 and 150 m²/g nickel.

Nickel aggregates were found to range between 9 and 26 micrometers and the catalyst of Example 4 was shown to have nickel aggregates which proved to be for 85% free of carrier particles.

Example 8

5 A 10% aqueous soda solution and a 3.5% aqueous nickel sulphate (calculated as nickel) solution in which kies-
selguhr (22 g per litre) had been blended were both
continuously pumped into a small precipitation reactor
(75 ml capacity) whilst the reactor was heavily agi-
tated (energy input 6 Watts per litre of solution).
10 The two liquids were fed into the reactor in such rates
that the pH in the precipitation reactor was 9.3. The
residence time was 0.5 minutes.

15 After precipitation the slurry contained about 4% of
solids and this slurry was continuously aged in a rela-
tively larger vessel (capacity 4.5 l) with moderate
stirring. The ageing temperature was 97°C and the pH
was 8.9. The average residence time in the ageing re-
actor was about 30 minutes.

20 After 1.5 hours the flows were stopped and 4.5 l of
slurry were filtered in a Büchner funnel under vacuum.
After filtration the solids (filter cake) were washed
with 4 litres of distilled water. The filter cake was
then dried overnight in an oven at 120°C.

25 Samples of the green filter cake were investigated by
electron microscopy (magnification 500 and 1000 x). The
photos showed small nickel/nickel compound aggregates
of which 80% were free of carrier particles and also
30 the original shapes of the siliceous skeletons were
largely uncovered by nickel/nickel compounds and freely
perceptible.

35 The green cakes were reduced at 400°C with a hydrogen
flow of 15 N* m³/kg Ni for 30 minutes.

* = (S.T.P.)

5 The active nickel surface area was determined by hydrogen chemisorption and yielded a value of 110 m²/g nickel. The average size of the nickel crystallites was calculated to be 3 nanometers and the size of the nickel/nickel compound aggregates was found to be 30 micrometers.

This catalyst had excellent properties for the hydrogenation of soybean and fish oils.

CLAIMS

1. Hydrogenation catalyst, containing 10-90 parts by weight of nickel/nickel compounds and 90-10 parts by weight of silica and having an overall active nickel surface of 70-200 m²/g, preferably more than 100 m²/g per gram nickel, characterized in that the catalyst comprises nickel/nickel compound aggregates with an average particle size ranging from 2 to 100 micrometers and that the nickel/nickel compound aggregates are for at least 60% free of carrier particles.
2. Hydrogenation catalyst according to claim 1, characterized in that the surface of the nickel/nickel compound aggregates is for at least 80% free of carrier particles.
3. Hydrogenation catalyst according to claim 1 or 2, characterized in that the nickel/nickel compound aggregates are for at least 90% free of carrier particles.
4. Hydrogenation catalyst according to any one of claims 1-3, characterized in that the average particle size of the nickel/nickel compound aggregates ranges between 5 and 25 micrometers.
5. Hydrogenation catalyst according to any one of claims 1-4, characterized in that the average nickel crystallite size ranges between 0.5 and 10 nanometers.
6. Hydrogenation catalyst according to any one of claims 1-5, characterized in that the nickel crystallite size ranges from 1 to 3 nanometers.

7. Process for preparing a nickel-based catalyst comprising an insoluble carrier and optionally a promoter, which process is carried out in at least two steps, to wit:

- 5 (i) A rapid precipitation step, in which under vigorous agitation the nickel hydroxide/carbonate is precipitated in a precipitation reactor with a mean residence time of 0.01 to 10, preferably 0.2 to 4.5 minutes, rather even less than 3.5 minutes, during
10 which the normality of the solution in the reactor, containing excess alkali, is between 0.05 and 0.5, preferably between 0.1 and 0.3 N and the temperature of the liquid in the precipitation reactor is kept between 5 and 95°, preferably between 20 and 55°C.
- 15 (ii) At least one separate, longer ageing step with a mean residence time in the post-reactor of 20 to 180 min, preferably between 60 and 150 min, and a temperature that remains between 60 and 10°, preferably between 90 and 98°C, after which the solid is separated,
20 dried and activated with hydrogen in a manner known per se.

8. Process according to claim 7, characterized in that the nickel salt solution to be precipitated contains 10-80 g nickel per litre.
25

9. Process according to claims 7 or 8, characterized in that the carrier is added in an amount of 20-200 g per litre.
30

10. Process according to any one of claims 7-9, characterized in that the solution of the alkaline compound contains from 30 to 300 g of anhydrous alkaline compound per litre.

11. Process according to any one of claims 7-10, characterized in that the alkaline solution contains sodium carbonate.
- 5 12. Process according to any one of claims 7-11, characterized in that the nickel compound is a salt of a mineral acid.
- 10 13. Process according to any of claims 7-12, characterized in that the carrier is silica.
14. Process according to claim 13, characterized in that the silica used is kieselguhr consisting for 50 to 90 wt.% of amorphous SiO_2 .
- 15 15. Process according to any one of claims 7-14, characterized in that during precipitation agitation takes place with a mechanical energy input of 5-5000, preferably 5-25 kilowatts per 1000 litres of solution.
- 20 16. Process according to any one of claims 7-14, characterized in that mechanical agitation is effected by jet mixing.
- 25 17. Process according to any one of claims 7-16, characterized in that the activation of the catalyst is carried out with hydrogen at a temperature between 250 and 500°, preferably between 300 and 400°C.
- 30 18. Process according to any one of claims 7-17, characterized in that precipitation is carried out continuously by dosing a carrier suspension in an aqueous nickel salt solution together with an alkaline solution in a small, vigorously rotating mixing pump and subsequently pumping the suspension
- 35 into one or more post-reactors.

- 5 19. Process according to claim 18, characterized in that two or more post-reactors are used, the temperature in the second and any following post-reactor being 5-15 centigrades lower than that in the first post-reactor.
20. Use of nickel catalysts as described in any of the preceding claims in the hydrogenation of unsaturated organic compounds.
